SUMMARY

This report was prepared to provide air pollution control executives, engineers, modelers, planners, researchers and meteorologists with some of the surface airflow climatological data and displays necessary for effective decision making.

The report is presented in three sections and four appendices. The sections contain charts showing seasonal predominant wind patterns over California and its coastal waters, airflow types for four air basins by season and time of day, and resultant wind diagrams for 47 stations by month and time of day.

The appendices contain a brief general discussion of surface airflow in California, definitions and conversion tables, an annotated bibliography, and surface wind summaries by season for 170 stations in California and six stations in adjacent states but near the California border.

INTRODUCTION

The Air Resources Board (ARB) is responsible for achieving and maintaining satisfactory air quality in California in cooperation with local air pollution control districts and the U.S. Environmental Protection Agency. The Board's control programs rely heavily on the assessment of air quality data in terms of trends and of the occurrences of pollutant concentrations in excess of those specified in the ambient air quality standards. These kinds of assessments require a knowledge of pollutant transport as well as the usualness or unusualness of the meteorological conditions under which the air quality measurements were taken. For example, it is important (from a regulatory standpoint) to realize that the frequent exceedances of the ozone standard at Palm Springs (in the Southeast Desert Air Basin) during the summer are due in part to transport of the pollutants from the South Coast Air Basin via the San Gorgonio Pass.

The planning, research, stationary source, and motor vehicle emission control elements of the Board's control program also need a variety of climatological services. Most of these services involve an assessment of climatological statistics of various kinds. Thus it is important to the success of these program elements that basic climatological data be readily available and appropriately summarized and analyzed.

To assist in meeting the above needs, the meteorological staff of the Aerometric Data Division presents three climatological summaries of California surface wind data in this report. The first summary (Section 1 -- Predominant Surface Wind Flow Patterns) consists of seasonal predominant wind flow patterns for the non-mountainous areas of the state. The second summary (Section 2 -- Air Basin Surface Airflow Types) consists of typical surface airflow typed patterns for the South Coast, San Francisco Bay Area, San Joaquin Valley, and Sacramento Valley Air Basins and statistics on their seasonal and diurnal frequency of occurrence. The third summary (Section 3 -- Three-Hourly Resultant Surface Wind Summaries) consists of diurnal and seasonal surface resultant wind flow data for 47 locations throughout and nearby California.

The formats and displays used for the above sections and for the appendices are explained in the first part of each presentation. Figures in the sections and appendices are labelled to indicate the appropriate section or appendix, e.g. 1a and 1b are in Section 1; A-1, A-2 are in Appendix A, etc.

A concise description of the climatic influences on the general surface airflow patterns in California is given in Appendix A.

The technical terms used in this report and physical processes associated with winds, which may be unfamiliar to some people, are defined in Appendix B. Conversion tables are also given in Appendix B to facilitate converting miles per hour (mph) to knots (kts) and to meters per second (mps).

An annotated bibliography is given in Appendix C. In general, the 23 references cited provide additional California surface wind climatological information and are available in technical libraries or from the originating agencies.

Tabulations of pertinent predominant and resultant surface wind data for the 176 locations in and near California used in this study are contained in Appendix D. An index is given on pages D3-D6.

The data displayed in this report were prepared with the user's needs in mind and are based on an extensive amount of meteorological record. The authors would welcome receiving any comments the user might have regarding the usefulness of the report's contents, the nature of its displays, etc.

This report complements the upper air climatology provided in the ARB report titled "Summary of California Upper Air Meteorological Data", December 1979 and the regional descriptive climatologies contained in the ARB Air Basin Climatology Series, 1974/5. When these climatologies are used in conjunction with each other they provide a comprehensive general picture of the weather and climate of California as they pertain to air pollution control activities. Specific local projects will benefit from on-site data measurements and interpretation by an air pollution meteorologist.

This report has been assembled in a format that can be converted into a loose leaf notebook so that, in the future, additional similar climatological displays can be incorporated into the basic document. It is envisioned that, periodically, as additional displays become available, such as those contained in Section 3 and Appendix D, they may be sent to recipients of this report. In this way additional useful climatological data may be made available to users with the minimum of delay. In an effort to plan for this eventuality, it is requested that recipients of this report who would like to receive these supplements, as they are published, please notify the Air Resources Board, Meteorology Section, P. O. Box 2815, Sacramento, CA 95812 (916-322-7457) so that they may be placed on the mailing list.

Section 1

PREDOMINANT SURFACE WIND FLOW

Predominant surface wind flow patterns have been prepared for the four seasons of the year using data from most stations in California and several nearby stations in other states where at least one full season of record is available. Predominant wind is defined as the direction of the mid-point of the 3-point sector (group of three contiguous points of the compass in a 16-point display) which holds the largest number of the total wind observations. For example, in the following portion of a wind rose:

<u>Direction</u>	<u>Percentage of Time</u>
N	1
NNE	3
NE	6
ENE	5
E	4

The predominant wind direction is ENE because the sector including the contiguous NE, ENE, and E directions contains the largest composite percentage of occurrence.

Charts for the four seasons are presented in Figure 1a (Winter), Figure 1b (Spring), Figure 1c (Summer), and Figure 1d (Fall). The location of the sites with wind data used in this analysis are shown in Figure D-1, Appendix D, and the data are contained in the tables in Appendix D. Additional pertinent climatological statistics are also contained in the tables (percentage frequency of occurrence of predominant wind, resultant wind, mean speeds, and persistence ratios). The predominant wind on a 16-point display can be considered as a sector prevailing wind, i.e. the sector with the greatest occurrence; a sector in this case being 67-1/2° or 3/16's of the compass rose. On an 8-point display the prevailing wind is considered as the predominant wind for purposes of this analysis.

The patterns presented (Figures 1a-1d) consist of wind streamlines for mostly the non-mountainous areas of California where the vast majority of measurements were taken. In several instances, streamlines are shown in mountainous zones where data substantiate continuous streamlines from non-mountainous zones. These are generally regions where interbasin transport of air is evident and important to air pollution control. Streamlines based on data are continuous; those portions that are not connected are based mostly on theoretical considerations. The final analyses are adjusted as necessary for compatibility with those as shown in the referenced documents (Appendix C). Streamlines are developed for the "California Coastal Waters" from buoy, ship, island and coastal station weather reports. The "California Coastal Waters" are noted on Figures 1a-1d and are defined in Appendix B.

Figure 1c

It is worthy of mention that caution has been exercised when interpreting wind data for a station with only one season of data available for analysis, as is the case at times herein. In a case where a season experienced anomalous weather the predominant wind data may not reflect the true climatological wind flow pattern shown in the charts above. For example, due to an extremely stormy winter in 1981/82, the winter seasonal data for Colusa (p. D-24) indicate upvalley (southerly) flow as the predominant flow and downvalley (northerly) flow as the secondary predominant flow. An analysis of long term Sacramento Valley winter wind data indicates that the secondary predominant wind more than likely represents the true climatological wind situation. These types of considerations were part of the overall data base analysis strategy used when preparing the seasonal predominant wind flows.

The contours of the mountainous zones of California are also noted on Figures 1a-1d and are, in general, delineated by the average height of the base of the summertime subsidence inversion. The inversion base normally slopes upward from the coastline to the interior. As a result, the elevations that bound the mountainous zones tend to slope upward from west to east. The mountainous zone boundary is well described by the 1,000-foot terrain contour along the coast. On the eastern side of the coastal ranges the boundary lies at about 2,000 feet above sea level and between 2,000 and 4,000 feet in the Sierras. In general, the mountainous zone contour is situated between 1,000 and 2,000 feet above the surrounding plain or valley floor. Physically, the non-mountainous zones depicted in Figures 1a-1d represent the areas influenced by the earth's atmospheric boundary layer associated with the valleys, plains, and deserts wherein air pollution can accumulate and pose a potential air quality problem.

Section 2

AIR BASIN SURFACE AIRFLOW TYPES

Airflow types and their percentage frequency of occurrence are contained in this section for the most heavily populated air basins by season for four times daily. This information was derived from meteorological maps showing the surface airflow patterns that have been prepared daily for 4 a.m., 10 a.m., 4 p.m., and 10 p.m. (PST) by the ARB meteorological staff since 1974. These maps are useful in determining when high air pollution concentration may occur and for making agricultural burning control decisions. When typed by recurring patterns and summarized by season and time of day they also provide air pollution climatological information that is helpful in studying pollutant transport and dispersion and in making planning decisions.

Airflow types and percentage occurrences from 1974 to 1977 were previously published in the ARB's "California Air Quality Data", July-September, Volume IX, No. 3, 1977 issue. Updated summaries with data from December 1977 through November 1981 are presented in this report.

With these updated summaries, the miscellaneous types are eliminated by sorting and placing them in the nearest appropriate airflow type; airflow types for the Sacramento Valley Air Basin are added, and a more rigorous interpretation of airflow patterns is made which results in the elimination/addition and modification of several airflow types. In addition, seasons are made to agree with the more meaningful California climatological interpretation: Winter (December, January, February), Spring (March, April, May), Summer (June, July, August), and Fall (September, October, November).

The new typing system used for this report is slightly different from the previously published work for the period 1974-1977 ("California Air Quality Data", Vol. IX, No. 3) so that the statistics for the two periods cannot be merged as is. In case it is desired to increase the data base of this report, the old type statistics may be merged with some success by using the type comparison scheme tabulated below where the old type is the 1974-77 data base and new type is the December 1977-November 1981 data base. The difference between the months making up the season of the two data bases is not considered significant for this purpose.

* miscellaneous

South Coast Air Basin

The airflow patterns in the South Coast Air Basin can generally be characterized by one of the seven directional types illustrated in Figure 2a. The percentage occurrence of these airflow types as they vary by 6-hourly intervals and by season of the year are contained in Table 2a. For instance, as shown in Table 2a, for percentage occurrence of Calm (Type VII), Offshore (Type III), and Downslope/Transitional (Type V) patterns are dominant in summer and fall during the early morning hours. These types allow pollutants to build up in the industrial and business areas and then move inland with the Sea Breeze (Type II) in the afternoon. This typical arrangement and sequence of winds leads to the maximum occurrence of ozone in the interior plains and valleys of the South Coast.

Due to the significant influence of emissions in the South Coast Air Basin on the neighboring air basins and coastal waters through wind transport this aspect was considered in the airflow typing. Note that in Figure 2a airflow in parts of the South Central Coast, San Diego, Southeast Desert Air Basins and coastal waters are depicted. These depictions may be helpful in assessing the airflow in these peripheral areas.

San Francisco Bay Area Air Basin

The airflow patterns in the San Francisco Bay Area Air Basin can generally be characterized by one of the seven types illustrated in Figure 2b. The percentage occurrence of these airflow types as they vary by 6-hourly intervals and by season of the year are contained in Table 2b. For instance, as shown in Table 2b, the percentage occurrence of Northwesterly (Types Ia and Ib) airflow is especially dominant in the early afternoons in spring, summer, and fall. This leads to the likelihood of some pollutant transport from the Bay Area into the Sacramento Valley and San Joaquin Valley Air Basins. Patterns that can lead to pollution episodes in the Bay Area Air Basin are Inflow (Type V), Outflow (Type VI), and Calm (Type VII), all characterized by weak airflow conditions.

San Joaquin Valley Air Basin

The airflow patterns in the San Joaquin Valley Air Basin can generally be characterized by one of the four directional types illustrated in Figure 2c. The percentage occurrence of these airflow types as they vary by 6-hourly intervals and by season of the year are contained in Table 2c. Examination of the data in Table 2c can uncover seasonal variations of consequence in airflow types. For example, the Northwesterly Upvalley (Type I) flow is predominant in summer while Calm (Type V) conditions predominate in winter. This reflects the prevailing stagnant conditions of winter which leads to a high incidence of valley fog and sulfates during that season.

Sacramento Valley Air Basin

The airflow patterns in the Sacramento Valley Air Basin can generally be characterized by one of the eight directional types illustrated in Figure 2d. The percentage occurrence of these airflow types as they vary by 6-hourly intervals and by season of the year are contained in Table 2d. Examination of the data in Table 2d can uncover seasonal and diurnal variations of consequence in airflow types. For example, the Sea Breeze (Type I) pattern dominates the wind flow in spring and summer especially in the afternoon, while in winter Calm (Type IX) conditions dominate the late evening and early morning atmosphere which reflect poor ventilation and increased air pollution.

Please note that due to rounding of percentages in Tables 2a-2d, the sum of hourly percentages for types will not always equal 100%.

The shaded areas in Figures 2a-2d indicate the mountainous zones as described in Section 1 of this report.

Figure 2d - SACRAMENTO VALLEY AIR FLOW PATTERN TYPES

Section 3

THREE-HOURLY RESULTANT SURFACE WIND SUMMARIES

Diagrams showing the monthly three-hourly resultant surface winds for 43 California stations and four nearby stations in other states are contained in this section. The stations selected had at least four years of appropriate surface wind data available for this type of analysis. The locations of these stations can be seen on the map contained in Figure 3a. An index of stations for which resultant wind diagrams and summaries is given in Table 3a.

The resultant wind is the vectorial average of all wind directions and speeds for a stated period of record. Three-hourly resultant winds as used in this section are hourly winds that have been summarized every three hours rather than being averaged over a 3-hour period. For example, for Arcata on page 26, the three-hourly resultant wind at 1 p.m. for January is the resultant of all winds observed at that hour and during that month over the period of record (1949-1977).

The three-hourly resultant winds were plotted on a hour/month diagram for each station and analyzed for speed (mph). A completed analysis for Bakersfield can be seen in the diagram on page 27. The climatological resultant wind for any hour of the year can be seen or interpolated from the information in the diagram. For example, for June 0300 PST, Bakersfield's resultant wind is interpolated as 360°/03 mph.

A summary of seasonal and annual three-hourly resultant winds for each station is tabulated below the resultant wind diagram for easy reference.

These diagrams and tables were originally prepared from the "resultant wind summary by hours" data contained in the Local Climatological Data (LCD) monthly summaries published by NOAA, National Climatic Center using the latest five years of data. These data were only available for the first order observation stations which are annotated in Table 3a (19 stations). The resultant wind data for the remaining 28 stations were calculated from wind roses and magnetic tape summaries on file at the ARB which are made up of a variable number of years of record.

It should be pointed out that in the case of Camp Pendleton (page 34), there were only two years of data available for the nighttime hours so that monthly resultant winds were not computed; however, seasonal resultant winds were computed for those hours to provide some diurnal continuity.

CALIFORNIA AIR RESOURCES BOARD
AEROMETRIC DATA DIVISION 4/84

ACKNOWLEDGEMENTS

The authors wish to gratefully acknowledge the contributions to this report made by the Air Resources Board meteorological staff; particularly to Warren Blier, Mark Borges, Dennis King and Karen Windsor for their valuable assistance in the extraction and keypunching of the basic wind summary data. Appreciation is expressed for the contributions of Jackie Garcia and Sharon Lantz who typed the manuscript; Greg Spencer and Eric Decetis provided graphic arts services; and John DaMassa provided electronic data processing assistance.

Thanks are also extended to Jim Goodridge (Department of Water Resources) who assisted in locating additional wind data and to Mike Basso and Avi Okin (Bay Area Air Quality Management District), Bob Swanson (Pacific Gas & Electric Company), and James Helt (Los Angeles Department of Water and Power) for providing wind data from their stations for inclusion in this report.

APPENDIX A

WIND FLOW IN CALIFORNIA

Macro-scale wind is air movement generated by large scale atmospheric pressure differences which are caused by the earth's rotation and differential heating of the earth's surface by the sun. The earth's rotation is constant while differential heating varies both with the latitude of an area and with the nature of the surfaces being heated such as land or water surfaces.

In terms of hemispheric atmospheric circulation, California lies in the latitudinal range of prevailing westerly winds. The North Pacific high pressure cell is the dominant influence on the low level wind flow of the Eastern North Pacific Ocean and neighboring land areas in middle latitudes, particularly during the summer. It is a semi-permanent feature of the Northern Hemispheric large scale atmospheric circulation pattern, and it produces a predominantly northwesterly flow of maritime air over the California coastal waters. During winter the Pacific high weakens and moves south so its influence is lessened somewhat resulting in weaker and less persistent northwesterly winds along the California coast than in the warm half of the year. The mean sea level barometric pressure patterns for winter and for summer over the Eastern North Pacific Ocean are shown in Figures A-1 and A-2, respectively.

This large scale circulation pattern is further modified to more westerly flow by continental influences as the air approaches the coast of California. The differential heating of the land area of California and the adjacent Pacific Ocean lying to the west enhances or weakens the predominant flow; enhancing it during the warm half of the year and weakening it during the cold portion.

Finally, on a local or regional basis the air flow in California is channeled by its mountain ranges with the predominant wind direction in a valley coinciding with the valley's longitudinal axis in one direction and the second most prevalent wind in line with the opposite direction, again parallel to the valley's axis.

The tendency for upvalley flow during hot months and downvalley flow during cold months is evident in the data contained herein. Also evident but less pronounced is the tendency for offshore flow during the coldest month, January. During the warm months, air flow is predominantly onshore because the land surfaces are generally warmer than the Pacific Ocean.

The coastal mountain ranges limit the accessible routes for maritime air into the interior of California. While these mountains are not especially high in comparison to the Sierra Nevada, they generally are higher than the subsidence inversion which stifles marine flow over the mountains, limiting entrance of the flow to the interior through breaks or low points in the coastal range. The principal break occurs in the San Francisco Bay area (Carquinez Straits) and the greatest part of the maritime air reaching the Central Valley of California traverses this area.

Figure A-1

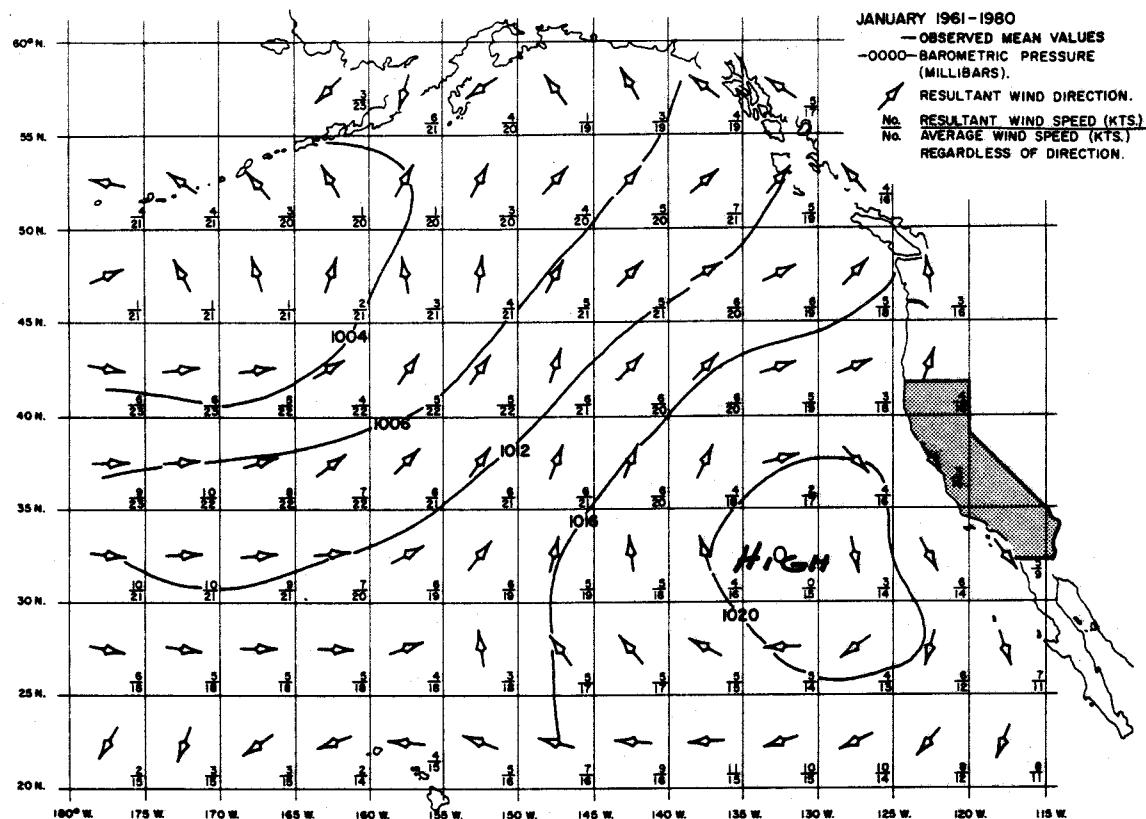

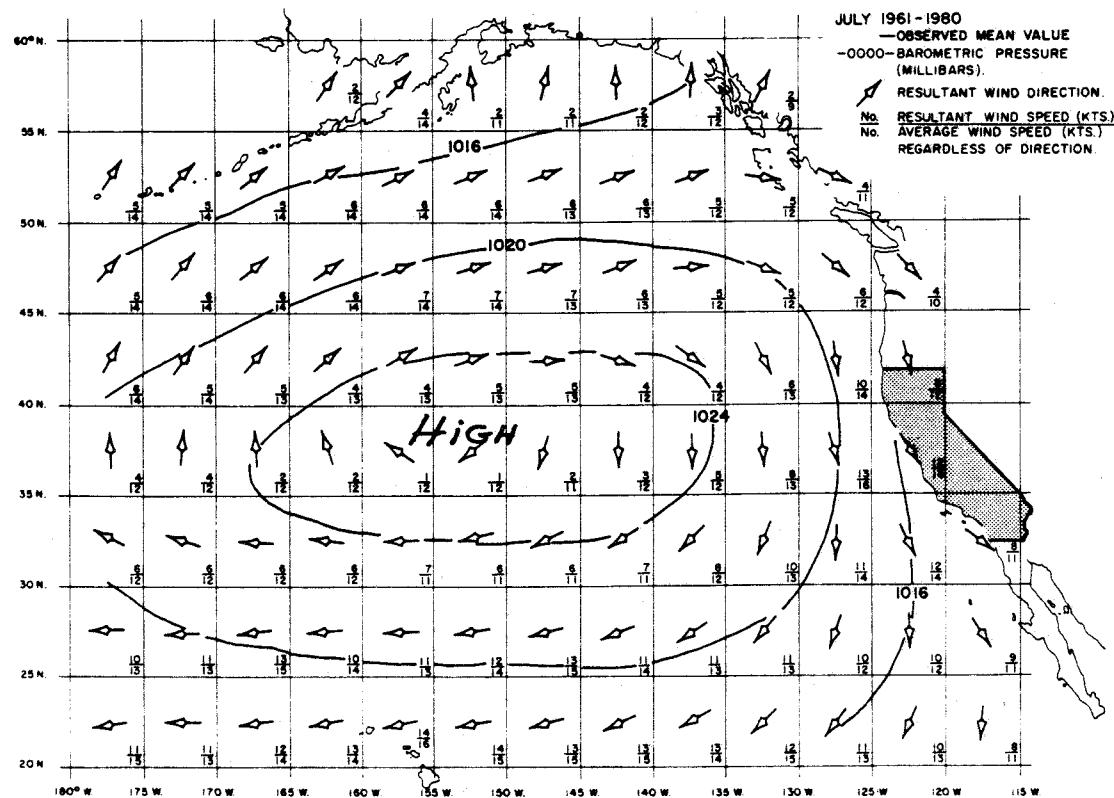

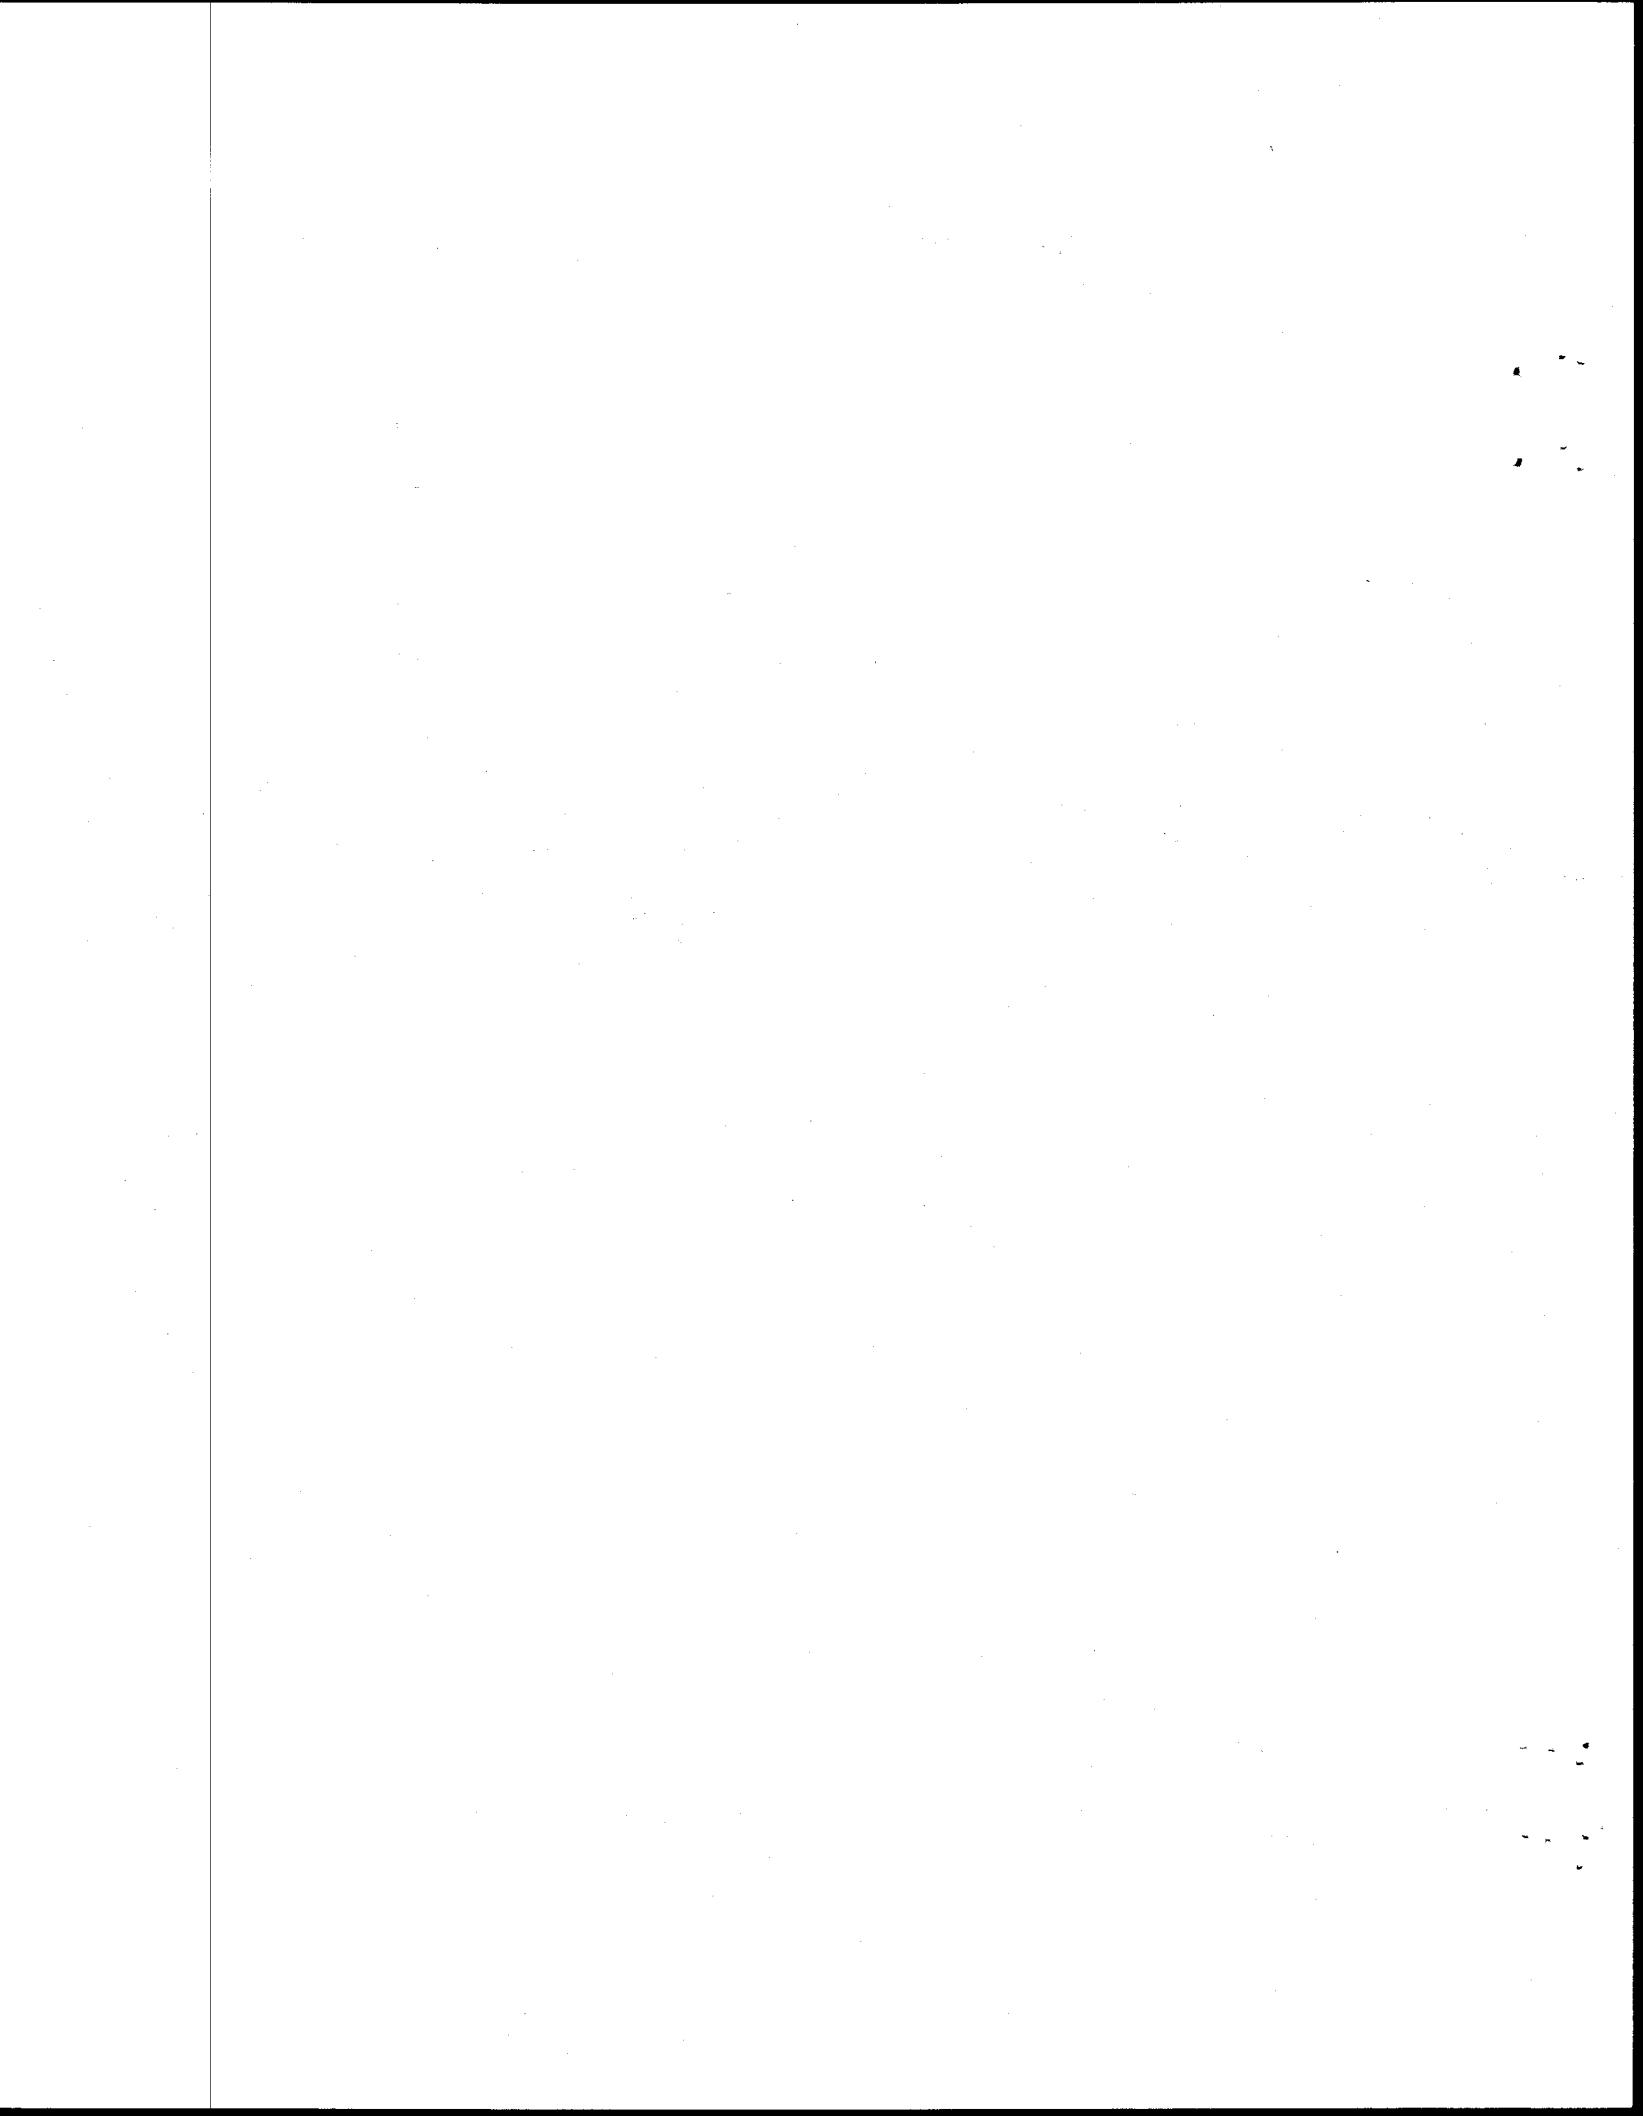

Figure A-2

Source: National Marine Fisheries Service (see Appendix C)

On a diurnal basis, the indicated prevailing seasonal air flows are most intense during the hottest part of the day during the hot months and during the coldest part of the day during the cold months. Thus, the upslope and upvalley flows shown in the Central Valley in July are most intense during the afternoon. The downvalley flow in January is more pronounced at night at the time of the strongest downslope cold air drainage.

It should be emphasized that the observed wind is the resultant air motion, at that time and place, from all influences on air flow, both local as well as the large scale effects mentioned above. The local effects include land-sea breezes, mountain-valley winds and terrain influences. The article by Defant (see Appendix C) provides an excellent description of these local influences on the wind along with a comprehensive list of references on the subject.

APPENDIX B
DEFINITIONS AND CONVERSION TABLES

Many of the definitions contained below were taken from the Glossary of Meteorology, edited by R. E. Huschke, American Meteorological Society, Boston, MA, 1959.

Adiabatic Processes:

A thermodynamic change of state of an air parcel in which there is no transfer of heat or mass across its boundaries. In an adiabatic process, compression always results in warming, expansion in cooling. The dry adiabatic lapse rate is about 1°C per 100 meters or about 5.4°F per 1,000 feet. When rising air cools to its dewpoint temperature, condensation begins, and latent heat is released, retarding the rate of cooling. The slower rate of cooling caused by the addition of latent heat to the rising air is called the wet, or saturation, adiabatic rate of cooling. The wet adiabatic lapse rate depends upon the quantity of moisture present in the air but in general may be considered to be about half the dry adiabatic lapse rate.

Bias Index:

Due to variable weather observational practices in the past some stations only recorded wind to the nearest 8-point compass while others tended to favor 8-points of a 16-point compass. Therefore the bias index described was developed for use in this report to indicate the tendency for wind directional observational bias in a wind data record. It is a number ranging from -1 to +1 and indicates the relative measure of bias towards an 8-point compass versus a 16-point compass. If all recorded wind directions, for the data record of a given station, are for the 8 cardinal directions (N, NE, E, SE, S, SW, W, NW), the bias index is +1. If all recorded wind directions are for the 8 non-cardinal directions (NNE, ENE, ESE, SSE, SSW, WSW, WNW, NNW), the bias index is -1. For records in between, the bias index is the appropriate number between -1 and +1. The bias index is calculated as follows:

Let N_1 = number of observations with non-cardinal directions
and N_2 = number of observations with cardinal directions

Then $R = N_1/N_2$ and

if R is greater than +1 then: Bias Index = $-(1 - 1/R)$

if R is less than or equal to +1 then: Bias Index = $1 - R$

EXAMPLE: The data for Costa Mesa (p. D-26) indicate there were 16,632 observations taken during the period of record. Referring to the annual "% of time" column it can be seen that 12,807 observations (77%) were from cardinal directions and that 3,825 observations (23%) were from non-cardinal directions. The ratio of non-cardinal to cardinal observations is:

$$R = 3,825/12,807 = 0.30$$

Since this ratio is less than 1.00 the bias index is:

$$\text{Bias Index} = 1 - R = 1 - 0.30 = 0.70$$

This indicates that the observations are biased towards the cardinal directions (N, NE, E, SE, S, SW, W, NW) and these directions are referred to as biased directions. In the case of a bias index less than -0.5 the bias would be towards the non-cardinal direction and the biased directions would be NNE, ENE, ESE, SSE, SSW, WSW, WNW, and NNW.

California Coastal Waters:

Defined as those Pacific Ocean areas between the California coastline and a line starting at the California-Oregon border at the Pacific Ocean thence to 42.0°N 125.5°W; thence to 41.0°N 125.5°W; thence to 40.0°N 125.5°W; thence to 39.0°N 125.0°W; thence to 38.0°N 124.5°W; thence to 37.0°N 123.5°W; thence to 36.0°N 122.5°W; thence to 35.0°N 121.5°W; thence to 34.0°N 120.5°W; thence to 33.0°N 119.5°W; thence to 32.5°N 118.5°W and ending at the California-Mexican border at the Pacific Ocean.

Convergence:

As used in this report, any line or zone along which the horizontal air flow is converging.

Diurnal:

Daily, especially pertaining to actions which are completed within 24 hours and which recur every 24 hours; thus, most reference is made to diurnal cycles, variations, ranges, maximums, etc.

Divergence:

As used in this report, any line or zone along which the horizontal air flow is diverging.

Inversion:

A layer of air in which the temperature increases continuously with altitude (a departure from the usual decrease of the ambient air temperature with altitude). The lowest altitude at which the increase is found is called the base of the inversion and the highest the top of the inversion. The difference between the temperature at the top of the inversion and at the base is a measure of the strength of the inversion. When this difference is equal to zero, it is considered to be isothermal. There are many types of inversions which generally are named for the cause for their formation such as radiation, subsidence, marine, and frontal.

Orographic Lifting:

The lifting of an air current by its passage up and over mountains.

Persistence Ratio:

The ratio of the resultant wind speed to the mean wind speed; ranging from 0 to 1. A high ratio indicates that the resultant wind is representative of the family of winds used to determine it. It is sometimes referred to as steadiness or consistency.

Predominant Wind:

The direction of the mid-point of the 3-point sector (group of three contiguous points of the compass in a 16-point display) which held the largest number of the total wind observations. The speed is the mean of the speeds of all winds in the predominant sector. The percentage frequency is the measure of the number of occurrences of winds in the predominant sector. The predominant sector represents 3/16ths of the compass or 67-1/2°.

Predominant Wind (alternate definition):

The same as predominant wind except that the midpoint is centered on the appropriate biased direction, i.e. on a cardinal direction for positive bias and on a non-cardinal direction for negative bias. If only alternate 8 points of the 16-point compass contain wind observations (i.e., bias index 1 or -1) it is considered that the intermediate points have a zero percentage frequency. In all cases above though the predominant sector represents 3/16ths of the compass or 67-1/2°.

If a station has a large positive or negative bias index the normal definition of predominant wind will usually select a direction for the predominant wind that is infrequently or never observed in the data. Therefore, if the absolute value of the bias index (see above) exceeds 0.50 the alternate definition is used.

Predominant Wind (secondary):

The secondary predominant wind is the predominant (or alternate definition) wind of the remaining portion of the compass display outside of the predominate wind sector. Therefore there is no overlap between the sectors associated with the predominant and secondary predominant winds.

Prevailing Wind Direction (or prevailing wind):

The wind direction most frequently observed (usually in a 16-point compass display) during a given period. The periods most frequently used are the observational day, month, season, and year. The mean speed of the wind in the prevailing direction can be used to provide the description of the prevailing wind.

Resultant Wind:

The vectorial average of all wind directions and speeds for a stated period of record.

Santa Ana:

A hot, dry, desert wind, generally from the northeast or east, especially in the pass and river valleys near Santa Ana, California, where it is further modified as a mountain-gap wind (a local wind blowing through a gap between mountains). It blows, sometimes with great force, from the desert regions east of the Sierra Nevada to Southern California and may carry a large amount of dust. In extreme cases this type of wind can affect the entire Southern California coastal plain from Point Conception to San Diego and is referred to as a Santa Ana condition in all areas. It is most frequent in winter; but can occur at any time of the year to some degree.

Sea Breeze:

A coastal local wind that blows from sea to land, caused by the temperature difference when the sea surface is colder than the adjacent land. Therefore, it usually blows on relatively calm, sunny, summer days; and alternates with the oppositely directed, usually weaker, nighttime land breeze. During periods of large scale onshore flow the sea breeze will enhance it producing persistent onshore winds.

Seasons:

- Winter (December, January, February)
- Spring (March, April, May)
- Summer (June, July, August)
- Fall (September, October, November)

Slope Winds:

A slope wind is a local diurnal wind that follows the slopes of all land forms. If the movement is up the slope the wind is referred to as an upslope wind and if the movement is down the slope as a downslope wind. Slope winds result from a horizontal temperature difference between the slope and the free air caused by warming (insolation) by day and cooling (radiation) at night. Accordingly, the movement of air is upslope during the day and downslope at night. The latter wind is sometimes referred to as a drainage wind. Slope winds are part of the mountain and valley wind system (see Valley and Mountain Winds).

Streamline:

A line whose tangent at any point in the atmosphere is parallel to the instantaneous velocity of the wind at that point.

Subsidence:

A descending motion of air in the atmosphere, usually with the implication that the condition extends over a rather broad area. Since the air is moving into higher pressures it is warmed by compression at the adiabatic rate and consequently dried. Large scale vertical motions are caused by an imbalance between the downward directed gravity force and the upward directed pressure gradient force. Since gravity is relatively constant at any given level subsidence is therefore generated by weak vertical pressure gradients normally found in the North Pacific high pressure cell. Subsidence is usually strongest during the summer when the Pacific high is at its maximum size.

Valley and Mountain Winds:

A system of diurnal winds along the axis of a valley, blowing uphill and upvalley by day, and downhill and downvalley by night; they prevail mostly in calm, clear weather. The upvalley component or "valley wind" usually sets in about an hour after sunrise and continues until about sunset, reaching its greatest strength at the time of maximum insolation on the slope in question. On southerly slopes it may reach 15 mph; on northerly slopes it is barely noticeable. The "valley wind" has a depth of some 500 feet, increasing uphill and is caused by the temperature difference between the air heated over the slopes and that at the same height in the free air. The air flows radially away from the summit and returns to the lowlands. The downvalley component or "mountain wind" at night is due to nocturnal cooling and is somewhat weaker, up to 9 mph, but is usually stronger a few hundred feet above the ground than at the surface.

Wind:

Air in motion relative to the surface of the earth. Since vertical components of atmospheric motion are relatively small especially near the surface of the earth, meteorologists use the term "wind" to denote almost exclusively the horizontal component. Vertical winds are always identified as such.

Wind Direction:

The direction from which the wind is blowing.

Wind Rose:

Any one of a class of diagrams designed to show the distribution of wind direction experienced at a given location over a considerable period; it thus shows the prevailing and predominant wind direction. The most common form consists of a circle from which eight or sixteen lines emanate, one for each compass point. The length of the line is proportional to the frequency of wind from that direction; the frequency of calm conditions is entered in the center. Many variations exist.

CONVERSION TABLES

Speed: Miles per hour to knots

Speed: Miles per hour to meters per second

mph	0	1	2	3	4	5	6	7	8	9

APPENDIX C

ADDITIONAL SOURCES OF SURFACE WIND DATA
AND
ANNOTATED BIBLIOGRAPHY

Surface wind data are gathered by many different groups in California; the most prominent of these being the National Weather Service (NWS), the Federal Aviation Agency (FAA), military weather services, air pollution control agencies, governmental forestry and agricultural agencies, universities, public utilities and fire/water districts. Most of the data gathered are available in raw and summary form from the National Climatic Center, Asheville, NC, or from the originating agency.

The following annotated bibliography contains references to documents that contain climatological summaries and discussions of surface winds in California which may be useful to environmental planners. The region of concern is the last item of each reference.

"Atlas of Climatic Charts of the Ocean", W.B. No. 1247, Washington, D.C., (Predominant wind flows of ocean areas) California coastal waters.

U.S. Weather Bureau (1957):

"Principal Tracks and Mean Frequencies of Cyclones and Anticyclones in the Northern Hemisphere", Research paper No. 40, Washington, D.C., 60 pp., (Mean storm tracks over northern hemisphere) California coastal waters and California.

APPENDIX D
SURFACE WIND SUMMARIES

Pertinent surface wind statistics for 176 locations in or near California with adequate data are tabulated alphabetically in this Appendix. The station locations (by number) are shown in Figure D-1 (page D-2) and location specifics are tabulated on pages D-3 through D-6.

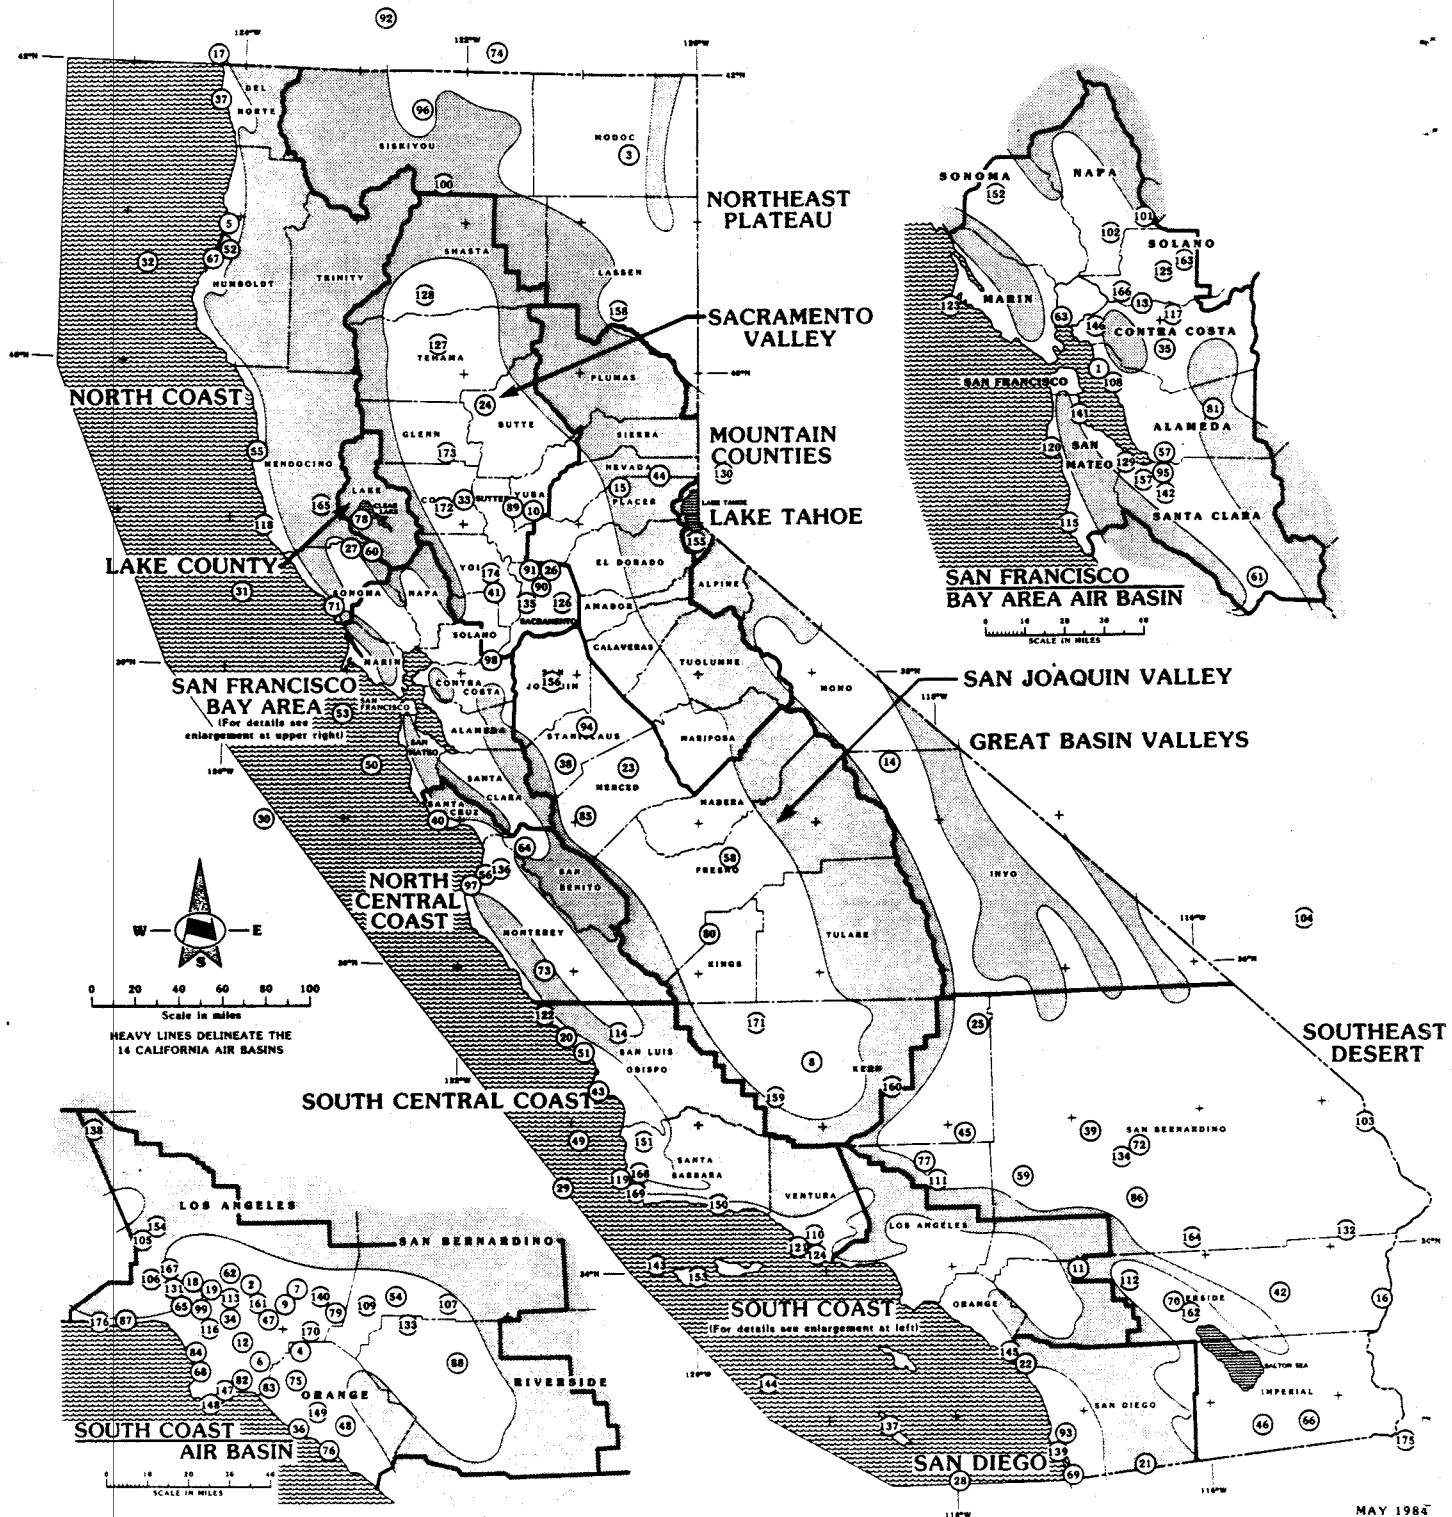

These data were used to prepare the predominant surface wind flow patterns contained in Section 1.

The surface wind statistics are tabulated for each station beginning on page D-8. These individual tables contain station specifics and data source information in the top section as follows: (using Alturas, on page D-10, as an example)

a. Station Name:	Alturas
b. Elevation:	4,375 feet msl (above mean sea level) -- If the elevation above ground of the anemometer is known it is entered here in parenthesis (in feet).
c. North Latitude:	41° 29'
d. West Longitude:	120° 34'
e. Period of Record:	December 1980 - November 1981
f. Number of Observations:	2,551
g. Observations per Day (if known):	7, between hours 0400 - 2200 PST
h. Bias Index:	0.21 (see Appendix B, Definitions, for explanation)*
i. Speed Units:	mph (miles per hour)
j. Source Codes:	data and summary format (see page D-7 for explanation)

* The "alternate definition" of predominant wind (see Definitions, Appendix B) is used in the wind summary tables if the bias index is greater than 0.50 or less than -0.50.
